Manda Hararo 2026 — signed phase-gradient evidence for shallow faulting

30-m Goldstein-filtered interferograms · signed wrapped-phase difference, positive ENE across the rift

Signed rift-perpendicular wrapped-phase differences after Sandwell & Price (1998), doi:10.1029/1998JB900008; cf. Xu et al. (2020), doi:10.1126/science.abd1690.
The ridge picker (results/fault_traces.json) uses the unsigned gradient magnitude |∇φ|.
The signed difference aliases where the cross-rift phase rate exceeds π per 30-m pixel (λ/4 of LOS per pixel); the white map veil and the gray profile band mark that zone, estimated from the unwrapped LOS. The forward-difference stencil shifts the signed map ≈15 m WNW of true gradient positions.
